Clinical Guideline

Management of Acute Croup in Children

Policy developed by: SA Child Health Clinical Network
Approved by SA Health Safety & Strategic Governance Committee on: 1 July 2013
Next review due: 31 May 2016

Summary
The Management of Acute Croup in Children Clinical Guideline is primarily aimed at medical staff working in any of primary care, local, regional, general or tertiary hospitals, however may be utilised or guide the care provided by other clinicians such as nurses. The information is current at the time of publication and provides a minimum standard for the assessment (including investigations) and management of acute croup, it does not replace or remove clinical judgement or the professional care and duty necessary for each specific case.

Keywords
Mucosal swelling, inflammation, larynx, cough, bark, inspiratory stridor, nebuliser, epiglottitis, laryngotracheitis, clinical guideline

Policy history
Is this a new policy? Y
Does this policy amend or update an existing policy? Y
Does this policy replace an existing policy? Y
If so, which policies?
Management of Acute Croup in Children, WCH Guideline

Applies to
All Health Networks
CALHN, SALHN, NALHN, CHSALHN, WCHN, SAAS

Staff impact
All Clinical, Medical, Nursing, Allied Health, Emergency, Dental, Mental Health, Pathology

Acute croup in children

April 2013
Disclaimer
The South Australian Paediatric Clinical Guidelines have been prepared to promote and facilitate standardisation and consistency of practice, using a multidisciplinary approach.

Information in this guideline is current at the time of publication.

SA Health does not accept responsibility for the quality or accuracy of material on websites linked from this site and does not sponsor, approve or endorse materials on such links.

Although the clinical material offered in this guideline provides a minimum standard it does not replace or remove clinical judgement or the professional care and duty necessary for each specific patient case. Where care deviates from that indicated in the guideline contemporaneous documentation with explanation should be provided.

This guideline does not address all the elements of guideline practice and assumes that the individual clinicians are responsible to:

- Discuss care with consumers in an environment that is culturally appropriate and which enables respectful confidential discussion. This includes the use of interpreter services where necessary.
- Advise consumers of their choice and ensure informed consent is obtained.
- Provide care within scope of practice, meet all legislative requirements and maintain standards of professional conduct.
- Document all care in accordance with mandatory and local requirements.

## Management Summary

<table>
<thead>
<tr>
<th>Severity</th>
<th>Management</th>
</tr>
</thead>
</table>
| **Mild** | Children with no stridor at rest or respiratory distress may be managed at home. Easy access to further medical review should be available.  
Oral dexamethasone – 0.15 mg/kg (max 10 mg) stat OR  
Prednisolone 1 mg/kg (max 50mg) daily for 2 days |
| **Moderate** | Dexamethasone – 0.15 mg/kg/dose orally stat (maximum 10 mg)  
OR Prednisolone 1 mg/kg kg (max 50mg) daily for 2 days  
*If the child is vomiting or is reluctant to drink:*  
Dexamethasone – 0.15 mg/kg/dose (max 10 mg) IM OR  
Budesonide - 2 mg nebulised  
Improvement should begin from 2 hours post administration. The anti-inflammatory effect of dexamethasone lasts **2-4 days**.  
*If improvement does not occur or stridor is worsening:*  
**Adrenaline (1:1000 strength) – 0.5ml/kg/dose to maximum of 5 ml via nebuliser**  
Improvement is seen within 10-30 minutes and the clinical effect lasts for 1-2 hours. Can be repeated every 15-20 minutes.  
**Oxygen** – if SaO₂ < 93% or significant respiratory distress  
**NB** Avoid upsetting the child if possible. Consider holding oxygen tubing a few centimetres from the child’s nose and mouth (blow by oxygen).  
Discharge if the child improves and the symptoms settle (see discharge criteria below). Observe for minimum of 3 hours following adrenaline administration.  
*If the child does not improve, admit to hospital or arrange transfer to a facility with paediatric beds (see admission criteria below)* |
| **Severe** | Involve **senior help** early (eg Consultant, ICU, MET team or consider calling for advice)  
**Oxygen** – high flow oxygen by mask or blow by oxygen  
**Adrenaline (1:1000 strength) – 5 ml via nebuliser** (can be repeated every 15-20 minutes as required)  
Dexamethasone – 0.15 mg/kg/dose orally stat (maximum 10 mg) OR  
Prednisolone 1 mg/kg (max 50mg) daily for 2 days  
*If the child is vomiting or is reluctant to drink:*  
Dexamethasone – 0.15 mg/kg/dose IM OR  
Budesonide - 2 mg nebulised (In children with severe croup, budesonide may be mixed with adrenaline and nebulised simultaneously)  
**Admit** or arrange transfer to a facility with paediatric beds.  
Repeated observations (½ - 1 hourly) of heart rate, respiratory rate, stridor, alertness and pulse oximetry are required until improvement occurs. Then manage as per instructions for moderate croup.  
*If poor response to adrenaline or rapid relapse despite repeated adrenaline doses, consider intubation.*  
Expert assistance (e.g. senior anaesthetic or ICU staff) should be alerted and discussion with MedStar Kids initiated.  
Repeat doses of adrenaline may be given pending intubation or retrieval. |

  What is croup? .......................................................................... 12
  How can it be treated? .............................................................. 12
  How long does it last? .............................................................. 12
Important points

- Croup is an acute illness characterised by mucosal swelling and inflammation of the larynx, subglottic area and upper trachea (laryngotracheitis)
- Croup is usually viral
- Non infective spasmodic croup occurs in a small subset of children.
- Children typically present with onset of barking cough, inspiratory stridor and variable increase in work of breathing.
- Croup mainly affects children 6 months to 3 years of age.
- Children with croup should be kept comfortable and unnecessary handling avoided
- Steroids are the cornerstone of management
- Nebulised adrenaline should be given for acute severe croup
- Senior help should be requested early in severe croup or if epiglottitis is suspected

Causes

- Croup is usually viral
  - parainfluenza types 1 and 3 (most common)
  - respiratory syncytial virus
  - metapneumovirus
  - influenza
  - adenovirus
- Non infective spasmodic croup occurs in a small subset of children.

Assessment

- Croup is a clinical diagnosis.
- Key features on history are:
  - acute onset of a seal-like barking cough
  - stridor
  - hoarseness
  - respiratory distress
  - fever

The child should not look toxic. While drooling is more typical of epiglottitis, some children may drool.

Examine the child on the parents’ lap to minimise distress.

Do not examine the throat with a tongue depressor.

Examine for:

- signs of toxicity
- respiratory effort
  - chest wall retractions
  - respiratory rate
o pulse oximetry (hypoxia from upper airway obstruction implies critical obstruction)
o heart rate
- inspiratory, expiratory or biphasic stridor
- degree of alertness

**Spasmodic croup** is difficult to differentiate from viral croup. Episodes can recur within the same night and for two to four successive evenings. A striking feature of spasmodic croup is its recurrent nature. The clinical course is usually benign.

**Main differential diagnoses**
The main differential diagnoses are
- acute epiglottitis
- bacterial tracheitis
- peritonsillar / retropharyngeal abscess
- foreign body aspiration
- anaphylaxis

**Acute epiglottitis** presents with a rapid onset of toxicity and upper airway obstruction with difficulty swallowing, a sore throat and a soft stridor. They are usually more comfortable sitting up/leaning forward. The most common cause is *H. influenzae* type B which is now uncommon in immunised children. If epiglottitis is suspected, call for senior help early. See the table below for a comparison of clinical signs.

</tbody>
</table>

**Acute bacterial tracheitis** presents as progressive respiratory distress with increasing stridor in a febrile toxic child in the context of prodromal viral respiratory tract infection. The usual causes are *H. influenzae* type B and *S. aureus*.

**Acute epiglottitis and bacterial tracheitis** are potentially fatal if missed and are airway emergencies. If in doubt, these more serious conditions should be excluded.

The primary goals in the management of **acute epiglottitis and bacterial tracheitis** are to secure the airway and administer appropriate antibiotics. Airway management and examination should be performed by an experienced multidisciplinary team ideally including someone skilled in paediatric intubation who can
secure the airway by intubation if necessary (preferably via inhalation technique). In these cases, the patient should not be laid down.

*Peritonsillar or retropharyngeal abscess* presents with fever, drooling, a change in voice quality and neck extension and painful neck movements.

*Foreign body aspiration* has an abrupt onset of cough without fever, often in a setting of the child playing with small objects.

*Anaphylaxis* presents as acute onset (minutes to hours) of an allergic reaction following exposure to an allergen and presenting with generalised urticaria, pruritus, swollen lips-tongue-uvula, respiratory compromise with dyspnoea and wheeze, hypotension, hypotonia, collapse and abdominal pain.

Assessment of clinical severity:

<td>Pink</td>
<td>May be cyanosed</td>
<td>Cyanosis without oxygen</td>
</tr>
</tbody>
</table>

Investigation
- Routine X-rays have no indication.
- Laboratory tests are not required as the diagnosis of croup is clinical.
- Additional investigations may be required to exclude one of the differential diagnoses.

Management
- Management depends on the age of the child, severity, time of day, parent capabilities, ability to access an urgent review i.e. access to phone, transport, ambulance etc and access to medical review.
- Children with croup of any severity should be made comfortable with minimal handling and upsetting the child.
- Hypoxia may be due to lower respiratory tract disease but if due to upper airway obstruction implies critical narrowing and is a medical emergency.
Management summary:

<table>
<thead>
<tr>
<th>Severity</th>
<th>Management</th>
</tr>
</thead>
</table>
| **Mild** | Many children older than 12 months may be managed at home. Easy access to further medical review must be available.  
Oral dexamethasone – 0.15 mg/kg (max 10 mg) stat OR  
Prednisolone 1 mg/kg (max 50mg) daily for 2 days |
| **Moderate** | Dexamethasone – 0.15 mg/kg/dose orally stat (maximum 10 mg)  
OR Prednisolone 1mg/kg kg (max 50mg) daily for 2 days  
*If the child is vomiting or is reluctant to drink:*  
Dexamethasone – 0.15 mg/kg/dose (max 10 mg) IM OR  
Budesonide - 2 mg nebulised  
Improvement should begin from 2 hours post administration. The anti-inflammatory effect of dexamethasone lasts 2-4 days.  
If improvement does not occur or stridor is worsening:  
**Adrenaline (1:1000 strength)** – 0.5ml/kg/dose to maximum of 5 ml via nebuliser  
Improvement is seen within 10-30 minutes and the clinical effect lasts for 1-2 hours. Can be repeated every 15-20 minutes.  
**Oxygen** – if SaO₂ < 93% or significant respiratory distress  
*NB* Avoid upsetting the child if possible. Consider holding oxygen tubing a few centimetres from the child’s nose and mouth (blow by oxygen).  
Discharge if the child improves and the symptoms resolve (see discharge criteria below)  
However, if the child does not improve, admit to hospital or arrange transfer to a facility with paediatric beds (see admission criteria below) |
| **Severe** | Involve senior help early (eg Consultant, ICU, MET team or consider calling for advice)  
**Oxygen** – high flow oxygen by mask or blow by oxygen  
**Adrenaline (1:1000 strength)** – 5 ml via nebuliser (can be repeated every 15-20 minutes as required)  
**Dexamethasone** – 0.15 mg/kg/dose orally stat (maximum 10 mg)  
OR Prednisolone 1 mg/kg kg (max 50mg) daily for 2 days *If the child is vomiting or is reluctant to drink:*  
Dexamethasone – 0.15 mg/kg/dose IM OR  
Budesonide - 2 mg nebulised (In children with severe croup, budesonide may be mixed with adrenaline and nebulised simultaneously)  
**Admit** or arrange transfer to a facility with paediatric beds.  
Repeated observations (½ - 1 hourly) of heart rate, respiratory rate, stridor, alertness and pulse oximetry are required until improvement occurs. Then manage as per instructions for moderate croup.  
If poor response to adrenaline or rapid relapse despite repeated adrenaline doses, consider intubation.  
Expert assistance (e.g. senior anaesthetic or ICU staff) should be alerted and discussion with MedStar Kids initiated.  
Repeat doses of adrenaline may be given pending intubation or retrieval. |
Primary and pre-hospital care:

- Assess the severity as per the above table
- Begin care as per the management table doing whatever is possible depending on circumstances (e.g. availability of oxygen)
- Consider giving Prednisolone as single dose

*N.B. There is no evidence that steam or humidified air speeds recovery. Steam is associated with burns and scalds and is therefore not recommended*

Indications for hospital assessment and/or admission

**Absolute:**

- Significant respiratory symptoms persisting at least 4 hours after steroid administration:
  - Audible stridor at rest
  - Significant respiratory effort
  - Oxygen requirement

**Relative:**

- young age, especially younger than 6 months
- poor oral intake and degree of dehydration
- social issues (e.g. distance from medical assistance, lack of transport)
- inadequate monitoring or follow up available
- significant parental anxiety
- repeated presentations within 24 hours

Criteria for discharge from emergency department

- No stridor at rest
- Normal pulse oximetry
- Normal colour
- Normal level of consciousness
- Demonstrated ability to tolerate fluids by mouth
- At least 3 hours after the administration of adrenaline
- Parents able to return for care if respiratory distress recurs at home
- Parents have access to telephone, ambulance and/or early medical review.

Discharge advice

- Parents should be advised that if child develops mild respiratory distress, it may be safe to drive to the nearest emergency department for treatment (See parent information sheet)
- If child develops severe croup with agitation and cyanosis, the parent should call 000 for ambulance transport to an emergency department
- Ensure the GP receives a discharge letter with all relevant clinical and management details
Inpatient care

- Repeated close monitoring of respiratory rate, heart rate, oxygen saturation, stridor, alertness, air entry, cyanosis and chest retractions
- Repeat doses of steroids are not usually required
- Care as per management table
- Discharge criteria are the same as for discharge from the emergency department except the child should be stable for a longer period if there is poor access to medical care.

Information for parents

Appendix 2 - Parent Information Sheet  
(Adapted from Women’s and Children’s Hospital information sheet)

What is croup?
Croup is usually caused by a virus which produces swelling of the child’s voice box (larynx) or windpipe (trachea). It usually affects children up to the age of five years. Croup often begins like a cold and then the child develops a harsh barking “croupy” cough. The voice is hoarse and the child may make a noise when breathing in (STRIDOR). The child may also have a sore throat and a fever. Generally a child is mildly unwell with a cough and fever but has some periods in a day when active. The stridor is most common when a child is upset, especially when the child suddenly awakens at night. A small group of children have continuous difficulty breathing or swallowing and need to see a doctor.

How can it be treated?
Attacks of coughing and stridor usually settle if a child is comforted. The child may be able to breathe better sitting up, in a parent’s arms or against two or three pillows. Warm drinks may help settle coughing attacks. If the child has a fever, paracetamol should be given. Do not smoke around the child. Antibiotics do not help, as the croup is caused by a virus.

How long does it last?
The acute period of croup lasts from two to five days, and is usually worse at night. The cough usually lasts longer, as the throat is often irritated even after the infection is gone.

A few children get repeated attacks of croup, sometimes without having a viral infection. There is no permanent damage from ordinary croup.

Children who have difficulty breathing when resting need urgent medical attention

You should seek medical help urgently if:
- Your child is getting worse.
- The chest is sucked in as the child breathes in, and the child is working hard to breathe.
- There is difficulty swallowing.
- Stridor is heard even though your child is resting quietly.
- Your child looks ill, and has a high temperature.
- You are concerned for any reason.
