South Australian Perinatal Practice Guideline

Bladder Management for Intrapartum and Postnatal Women

© Department for Health and Ageing, Government of South Australia. All rights reserved.

Note:
This guideline provides advice of a general nature. This statewide guideline has been prepared to promote and facilitate standardisation and consistency of practice, using a multidisciplinary approach. The guideline is based on a review of published evidence and expert opinion.

Information in this statewide guideline is current at the time of publication.

SA Health does not accept responsibility for the quality or accuracy of material on websites linked from this site and does not sponsor, approve or endorse materials on such links.

Health practitioners in the South Australian public health sector are expected to review specific details of each patient and professionally assess the applicability of the relevant guideline to that clinical situation.

If for good clinical reasons, a decision is made to depart from the guideline, the responsible clinician must document in the patient’s medical record, the decision made, by whom, and detailed reasons for the departure from the guideline.

This statewide guideline does not address all the elements of clinical practice and assumes that the individual clinicians are responsible for discussing care with consumers in an environment that is culturally appropriate and which enables respectful confidential discussion. This includes:

- The use of interpreter services where necessary,
- Advising consumers of their choice and ensuring informed consent is obtained,
- Providing care within scope of practice, meeting all legislative requirements and maintaining standards of professional conduct, and
- Documenting all care in accordance with mandatory and local requirements

Explanation of the aboriginal artwork:
The aboriginal artwork used symbolises the connection to country and the circle shape shows the strong relationships amongst families and the aboriginal culture. The horse shoe shape design shown in front of the generic statement symbolises a woman and those enclosing a smaller horse shoe shape depicts a pregnant women. The smaller horse shoe shape in this instance represents the unborn child. The artwork shown before the specific statements within the document symbolises a footprint and demonstrates the need to move forward together in unison.

Purpose and Scope of PPG

This guideline aims to provide clinicians with a stepwise approach for the assessment and management of bladder function during the intrapartum and postnatal periods.

Australian Aboriginal Culture is the oldest living culture in the world yet Aboriginal people continue to experience the poorest health outcomes when compared to non-Aboriginal Australians. In South Australia, Aboriginal women are 2-5 times more likely to die in childbirth and their babies are 2-3 times more likely to be of low birth weight. The accumulative effects of stress, low socio economic status, exposure to violence, historical trauma, culturally unsafe and discriminatory health services and health systems are all major contributors to the disparities in Aboriginal maternal and birthing outcomes. Despite these unacceptable statistics the birth of an Aboriginal baby is a celebration of life and an important cultural event bringing family together in celebration, obligation and responsibility. The diversity between Aboriginal cultures, language and practices differ greatly and so it is imperative that perinatal services prepare to respectively manage Aboriginal protocol and provide a culturally positive health care experience for Aboriginal people to ensure the best maternal, neonatal and child health outcomes.
Flowchart I: Bladder Management for Intrapartum and Postnatal Women

First stage of labour
- Encourage 2 hourly voids and document void
- If unable to void and bladder palpable (max 4 hours) perform in/out catheterisation
- If further urinary catheter required, leave in situ
- Consider IDC with epidural analgesia

Second stage of labour
- Encourage woman to void prior to commencing second stage
- In/out catheter prior to all assisted births
- In/out catheter if prolonged second stage (> 2hrs)
- Remove IDC prior to active pushing (deflate balloon fully)

No urinary catheter or post IDC removal
- Screen all women at 4 hours for risk factors and symptoms of urinary retention (see abnormal void parameters below)
- Encourage voiding by non-invasive measures (adequate analgesia, hydration, privacy)
- Encourage women to void within 2-3 hours (max 6 hours)

Indications to reinsert IDC immediately post-birth
- Excessive perineal trauma
- 3rd and 4th degree tears (leave in situ 12 hours)
- Epidural, spinal or pudendal block analgesia for birth with no sensation to void and Bromage score > 0 (review IDC removal 6 hours after birth)

Normal postpartum void parameters
- 2 consecutive voids > 200mL
- No symptoms of abnormal voiding function

No further action unless symptoms of abnormal voiding function occur later

Abnormal void parameters
- Unable to or straining to void
- Altered sensation to void
- Dysuria (pain with voiding)
- Slow or stop/start flow
- Small voids (< 200mL)
- Incomplete emptying
- Displaced urethra fundus

Postnatal Management of Abnormal Voidsing Function
Bladder Management for Intrapartum and Postnatal Women

Flowchart II: Postnatal management of abnormal voiding function

Symptoms of incomplete emptying, urinary retention or unable to void at 6 hours post-birth or IDC removal

- In/Out catheter to assess residual void volume within 10 minutes of void (80% of total bladder capacity should be voided)
- Consider leaving IDC in situ if bladder over-distension or contributing factors unlikely to resolve imminently (e.g., poorly controlled pain, excessive perineal oedema, poor mobility)
- Commence 24 hour fluid balance chart
- Urinalysis. If positive Nitrites send for MC&S to exclude urinary tract infection.

Record void and void volume, urinary incontinence and encourage woman to void 2 hourly (max 6 hours)

Unable to void after a further 6 hours
- Insert IDC on free drainage.
- Allow to drain and assess volume:
  - Drainage > 500mL in 10 minutes - leave IDC in situ for 24 hours
  - Drainage > 1000mL in 10 minutes - leave IDC in situ for 48 hours
- Send urine for MC&S
- Await results and review with medical team re need for antibiotics

TRIAL OF VOID
- Fluid balance chart, adequate fluid intake (1.5-2 litres) daily
- Encourage voiding by non-invasive measures (adequate analgesia, hydration, privacy)
- Encourage women to void within 2 hours (max 4 hours):
  - Document volume and time of void.
  - Assess residual void volume within 10 minutes of void by in/out catheter or real-time bladder scanner
  - Report residual > 100mL and bladder over-distension > 600mL to medical officer or team leader

High post-void residuals or unable to void
- Consider free drainage, catheter valve (flip flop) or intermittent self-catheterisation
- Review medical team, Continence team, Urology nurse or specialist in bladder retraining

Normal void parameters
- At least three consecutive voids (>200mL)
- Voided 80% or more total bladder capacity
- No symptoms of abnormal voiding function

No further action unless symptoms of abnormal voiding function occur later
Flowchart III: Intermittent Self-Catheterisation Algorithm

The management of women undertaking ISC should include medical team and specialist in bladder re-training

Aim of ISC:
- Ensure regular and complete bladder emptying
- Prevent bladder over-distension
- Restore bladder function

Bladder over-distension needs to be avoided:
- The total voided volume and the urinary residual is less than 600mL
- The woman will need to void, then insert the in/out catheter immediately post-void
- Start with daytime active void every 4 hours and urine residual

Frequency of ISC:
- Depends on bladder volume, fluid intake, post void residual, urodynamics parameters (compliance, detrusor pressure)
- Woman voids every 4 hours and performs ISC within 10 minutes
- Woman charts all voided volumes and residuals
- If total bladder capacity > 600mL
  - Advise woman to increase void to every 3 hours (with ISC for residual urine)
- Reduce and review oral intake to 2L/day
- Initially overnight void and residual measurements may be necessary to avoid bladder over-distension
- Check for medical causes if polydipsia and polyuria

Review ISC residual volumes over 2 days prior to reducing frequency of ISC:
- Commence program with ISC every 4 hours
- Reduce ISC to QID when post-void residuals < 100mL
- Reduce ISC to TDS (mane, midday, nocte) when post-void residuals < 100mL
- Reduce ISC to BD (mane, nocte) when post-void residuals < 100mL
- Reduce ISC to nocte (immediately prior to bed after last void of the day) when post-void residuals < 100mL
- Cease ISC when 2 consecutive night post-void residuals < 100mL
If concerns or transient urinary retention, advise the woman to measure void and residual urine and report to the Confinence Nurse Advisor, Midwife or Doctor

Professional management and follow-up:
- Confinence Nurse Advisor, Midwife or Doctor to assess woman's progress and discuss ongoing ISC program
- Follow-up phone contact with the woman for ongoing bladder and ISC re-training program

Inform woman it is essential to drink 2L of fluid every day
Excessive oral intake will increase diuresis and frequency of catheterisations

Woman follows good bowel care, constipation is avoided
Summary of Practice Recommendations

Women require assessment of normal voiding function in the intrapartum and postnatal period. Clinicians need to assess physiological, neurological and mechanical causes which increase the risk of urinary retention. Abnormal void parameters require assessment of residual void volume by in/out urinary catheter or real time bladder scanner. Women who continue to have high post void residuals or retention should be reviewed by the medical team and offered a choice between urinary catheter or intermittent self-catheterisation.

Background

The early identification of voiding dysfunction in the intrapartum and postnatal period reduces the risk of bladder over distention, persistent urinary retention and irreversible damage to the bladder, recurrent urinary tract infections and permanent voiding difficulties.

Normal voiding function

Normal voiding function includes micturition up to 8 times in 24 hour period. However, in the first 24 – 48 hours following birth, diuresis is increased. Women average 300-400mL with each void with 80% of total bladder capacity passed.

Normal postpartum void parameters:
- Two consecutive voids > 200mL
- No symptoms of abnormal voiding function (see below)

Abnormal voiding function

Void dysfunction, in particular postpartum urinary retention occurs in 10-15% of women. Abnormal voiding function symptoms include:
- decreased or absent sensation to void
- unable to or straining to void
- slow or stop-start urine flow
- frequency and urgency
- small void volumes (< 200mL)
- feeling of incomplete emptying
- displaced uterus
- pain with voiding (dysuria)

Risk Factors for Postpartum Voiding Dysfunction

Clinicians need to assess for physiological, neurological or mechanical factors which increase the risk of urinary retention. Detailed assessment of a woman’s voiding function is required.
- Prior history of void dysfunction
- First vaginal birth
- Epidural, spinal or pudendal block in labour
- Assisted vaginal delivery or shoulder dystocia
- Prolonged length of active first stage (> 11 hours) or second stage active pushing (> 2 hours)
- Excessive perineal trauma: obstetric anal sphincter injury, large episiotomy, para-urethral tear, clitoral tear, significant oedema, haematoma
- Birth weight > 3.8kg
- Urinary catheterisation in labour
- Change in void parameters post-birth (see Abnormal voiding function symptoms above)
Management

Women require assessment of normal voiding function in the intrapartum and postnatal period. See Flowchart I.

Intrapartum management

Women should be encouraged to actively void two hourly in labour. Document voids. A large proportion of women with epidural, spinal or pudendal blocks will have some negative impact on bladder function in the intrapartum and postpartum period. Women unable to actively void 2 hourly or with a palpable bladder require in/out catheterisation or IDC insertion. All urinary catheters should be deflated and removed prior to active pushing in second stage.

Postnatal bladder management

Initial postnatal assessment

All women should be actively encouraged to void 2 hourly following birth or catheter removal. Postpartum void review assesses the normal void function of women following birth or removal of urinary catheter. Document 1st and 2nd voids; assess and review voiding parameters. Report alteration in sensation to void, difficulty with initiating void, altered flow, incomplete emptying, urgency, small void volume and frequency of void. Assess for displaced uterine fundus.

If normal postpartum void parameters are met, no further action is required unless symptoms of abnormal voiding function occur later.

If a woman has not voided at 4 hours from last recorded void or urinary catheter removal, commence non-invasive measures for a further 2 hours:

- Adequate analgesia
- Hydration
- Privacy

Note: If a woman demonstrates signs of acute urinary retention at 4 hours from last recorded void, waiting a further 2 hours prior to intervening is not required.

Additional considerations

Women with dense epidural, spinal or pudendal blocks may require urinary catheterisation up to 6 hours post birth. Women should be assessed for adequate mobility (Bromage score = 0), and normal sensation to void prior to urinary catheter removal. Obstetric anal sphincter injuries require urinary catheter to remain in situ for 12 hours (see ‘Third and fourth degree tear management’ guideline in A to Z index at www.sahealth.sa.gov.au/perinatal).

Abnormal voiding function (see Flowchart II)

If a woman is unable to void or has symptoms of abnormal voiding at 6 hours post-birth or IDC removal (or demonstrates signs of acute urinary retention at 4 hours from last recorded void), assessment of post-void residual volume is required within 10 minutes of void using in/out catheterisation or real-time bladder scanner. (The standard bladder scanner may report on echogenic uterine debris when measuring urinary residuals and whilst less invasive, is not as reliable as in/out catheterisation as a measurement tool.)

Consider leaving urinary catheter in situ if bladder overdistension or other contributing factors are unlikely to resolve imminently (e.g. poorly controlled pain, excessive perineal oedema, poor mobility).

Commence fluid balance chart.
Perform urinalysis to exclude nitrites. If nitrite positive, send urine for MC&S. Await results and review with medical team re need for antibiotics.

**Ongoing abnormal voiding function (see Flowchart II)**

**Indwelling Catheter**

If woman is still unable to void after a further 6 hours (i.e. 12 hours post-birth or original IDC removal and 6 hours following in/out catheter), insert an IDC on free drainage. Assess and document urine volume for the first 10 minutes following insertion.

Bladder drainage will guide timeframe for catheter management and trial of void:
- Drainage > 500ml in 10 minutes - leave IDC in situ for 24 hours
- Drainage > 1000ml in 10 minutes - leave IDC in situ for 48 hours

Send urine for MC&S. Await results and review with medical team re need for antibiotics. Plan subsequent trial of void with medical team.

**Trial of void following IDC removal**

Report residuals > 600mL and/or bladder over-distension to medical officer or team leader

Continue fluid balance chart.

Encourage voiding by non-invasive methods (analgesia, hydration, privacy).

Encourage woman to void within 2 hours post-IDC removal (maximum 4 hours)

Measure the residual volume of urine in the bladder within 10 minutes of voiding with an in/out urinary catheter or real time bladder scanner. Two to three consecutive voids with normal void parameters are required. If after the first 2 voids, residual urine volumes are low, it is reasonable to consider measuring the 3rd void volume without assessment of residual volume. This decision should be made in consultation with a medical officer or continence specialist.

If normal post-partum void parameters are met, no further action is required unless symptoms of abnormal voiding function occur later.

**Persistent Postpartum Urinary Retention (see Flowchart II)**

Women with the following trial of void parameters need to be reviewed by the medical team and offered a choice between indwelling urinary catheter (e.g. catheter valve) or intermittent self-catheterisation.
- High post-void residuals (> 100mL)
- Bladder overdistension (total volume > 600mL)
- Urinary retention

Women should then be referred to a specialist in bladder retraining for ongoing management (e.g. Continence team, Urology Nurse, Stomal Therapist, Physiotherapist).

**Intermittent self- catheterisation (ISC) (see Flowchart III)**

Management of a woman undertaking ISC should include the medical team and a specialist in bladder retraining.

Obtain the woman’s consent and educate her in ISC.

Inform woman it is essential to drink 2L of fluid every day. Excessive oral intake will increase diuresis and frequency of catheterisations.

Women should actively void every 4 hours and perform ISC immediately after voiding (> 10 minutes is measuring renal perfusion and not urine residual). Chart both voided volume and residual urine measured by ISC.
Bladder Management for Intrapartum and Postnatal Women

Avoid bladder over-distension (total void and residual volumes should be < 600 mL). Overnight void and residual measurements may be necessary to avoid bladder over-distension initially. If total bladder capacity > 600mL, advise woman to void every 3 hours (with ISC for residual urine), and ensure oral intake is only 2L/day.

Frequency of catheterisation depends on bladder volume, fluid intake, post-void residual, urodynamic parameters (compliance, detrusor pressure). Frequency of catheterisation is decreased when void residuals are less than 100mL for 2 days at each level:

- Commence program with ISC every 4 hours
- Reduce ISC to QID when post-void residuals < 100mL
- Reduce ISC to TDS (mane, midday, nocte) when post-void residuals < 100mL
- Reduce ISC to BD (mane, nocte) when post-void residuals < 100mL
- Reduce ISC to nocte (immediately prior to bed after last void of the day) when post-void residuals < 100 mL
- Cease ISC when 2 consecutive night post-void residuals < 100mL

Check for medical causes if polydipsia and polyuria.
Send urine for MC&S if suspicion of urinary tract infection.
Ongoing bladder and ISC retraining program follow-up is required.
