IV to Oral Switch Clinical Guideline for adult patients: Can antibiotics S.T.O.P.

Version No.: 1.1
Approval date: 23 October 2017
Disclaimer

This guideline provides advice of a general nature. This statewide guideline has been prepared to promote and facilitate standardisation and consistency of practice, using a multidisciplinary approach. The guideline is based on a review of published evidence and expert opinion.

Information in this statewide guideline is current at the time of publication.

SA Health does not accept responsibility for the quality or accuracy of material on websites linked from this site and does not sponsor, approve or endorse materials on such links.

Health practitioners in the South Australian public health sector are expected to review specific details of each patient and professionally assess the applicability of the relevant guideline to that clinical situation.

If for good clinical reasons, a decision is made to depart from the guideline, the responsible clinician must document in the patient’s medical record, the decision made, by whom and detailed reasons for the departure from the guideline.

This statewide guideline does not address all the elements of clinical practice and assumes that the individual clinicians are responsible for:

- Discussing care with consumers in an environment that is culturally appropriate and which enables respectful confidential discussion. This includes the use of interpreter services where necessary,
- Advising consumers of their choice and ensure informed consent is obtained.
- Providing care within scope of practice, meeting all legislative requirements and maintaining standards of professional conduct and
- Documenting all care in accordance with mandatory and local requirements.
Background

Why Switch From Intravenous to Oral Antibiotic Therapy?

To manage serious infections in hospital most clinicians use intravenous (IV) antibiotics initially to ensure an optimal concentration of antibiotic at the site of infection. Inappropriate antibiotic use is recognised as a key driver of antimicrobial resistance. Unnecessarily prolonged courses of IV antibiotics are also associated with increased length of hospital stay, increased costs of nursing, pharmacy and medical time in the insertion of IV lines, preparation, dispensing and administration of IV agents and the increased morbidity and mortality associated with IV line infections [1-3].

To optimise antibiotic use, a switch from IV antibiotics to oral therapy in the appropriate patient has a number of advantages. These include a shorter length of hospital stay with the associated reduction in morbidity and mortality, a reduction in staff workload and a reduction in antibiotic costs [1, 4-6].

When to Switch

The optimal time to consider switching a patient to oral therapy is after 2 to 4 days of intravenous therapy. This period of time allows the clinician to evaluate the patient’s microbiology results and assess their response to treatment. A large number of clinical trials support the early switching to oral antibiotics after this period of time with equal treatment efficacy and no adverse effects on patient outcome [2, 3, 7].

The flow chart in this guideline aids the clinician in deciding if it is safe to switch a patient to oral antibiotics. A patient must meet a number of criteria prior to switching:

- Display signs of clinical improvement (Box 1)
- Able to tolerate oral therapy (Box 2)
- Not have a condition in which higher concentrations of antibiotic are required in the tissue or a prolonged course of IV therapy is essential (Box 4)

There are a number of conditions in which a switch to oral therapy should be considered including:

- Pneumonia
- Skin and soft tissue infections
- Urinary tract infections
- Uncomplicated Gram negative bacteraemia
- Intra-abdominal infection without deep seated collections

A consultation with the Infectious Diseases team or a clinical microbiologist at SA Pathology can provide guidance regarding the suitability of switch to oral therapy and the appropriate agent. The table in Box 3 also provides a guide for selection of the appropriate oral agent. It is important that the clinician reviews any microbiology results available prior to the change.

When selecting an antibiotic it is recommended that the clinician follow the antimicrobial creed of **MINDME** [8]:

| M | Microbiology guides therapy wherever possible |
| I | Indications should be evidenced based         |
| N | Narrowest spectrum therapy required          |
| D | Dosage individualised to the patient and appropriate to the site and type of infection |
| M | Minimise duration of therapy                 |
| E | Ensure oral therapy is used when clinically appropriate |
Definitions and acronyms

bd       Twice daily
CRP      C-reactive protein
IV       Intravenously
qid      Four times daily
tds      Three times daily
WBC      White blood cells

Standards

The following National Safety and Quality Health Service Standard (NSQHSS) standards apply:

Standard 3 – Preventing & Controlling Healthcare Associated Infections

> Criterion 3.14 – Developing, implementing and regularly reviewing the effectiveness of the antimicrobial stewardship system.

Standard 4 – Medication Safety

> Criterion 4.1 – Developing and implementing governance arrangements and organisational policies, procedures and/or protocols for medication safety, which are consistent with national and jurisdictional legislative requirements, policies and guidelines.

Principles of the standards

Standard 3 aims to prevent patients from acquiring preventable healthcare associated infections and effectively manage infections when they occur by using evidence-based strategies that are based on the risk to both patients and staff.

Standard 4 aims to ensure competent clinician safely prescribe, dispense and administer appropriate medicines to informed patients and carers.
Patients who have negative blood cultures and have received ≥ 48 hours of IV therapy may be eligible to STOP or switch to oral therapy. Use this guideline to select appropriate patients - important exclusions apply (see Box 4).

**Box 1**

**Signs of clinical improvement**

- Afebrile (temp >36°C and <38°C for past 48 hours)
- CRP trending down
- Stable immune response (WCC > 4 and <12 x 10^9 cells/L or trending towards normal range)
- No unexplained tachycardia
- No unexplained hypotension
- No tachypnoea

**Review therapy and investigations.** Consult ID/micro if necessary.

**Box 2**

**Tolerating oral medicines**

- Patient is not nil by mouth
- Patient is tolerating oral food or enteral feeding
- Oral absorption is not compromised (e.g. diarrhoea, vomiting, malabsorptive disorder, unconscious, swallowing disorder)

*Enteral feeding: consult pharmacy for advice on suitable formulation and administration method.*

**Box 3**

**Common oral antibiotic options**

Use the following guide to select appropriate oral therapy

Note: Doses provided are for normal renal function – refer to the Australian Medicines Handbook or the Therapeutic Guidelines:

**Antibiotic for dosing in renal impairment**

The following IV drugs have equivalent oral doses:

- Azithromycin, Linezolid, Flucnazole, Trimethoprim/Sulfamethoxazole

^ Consider patient allergy status when converting to a penicillin.
